# Process

**Process Scheduling**

**Representation of Process Scheduling**

**Schedulers**

**Addition of Medium Term Scheduling**

**Process Creation**

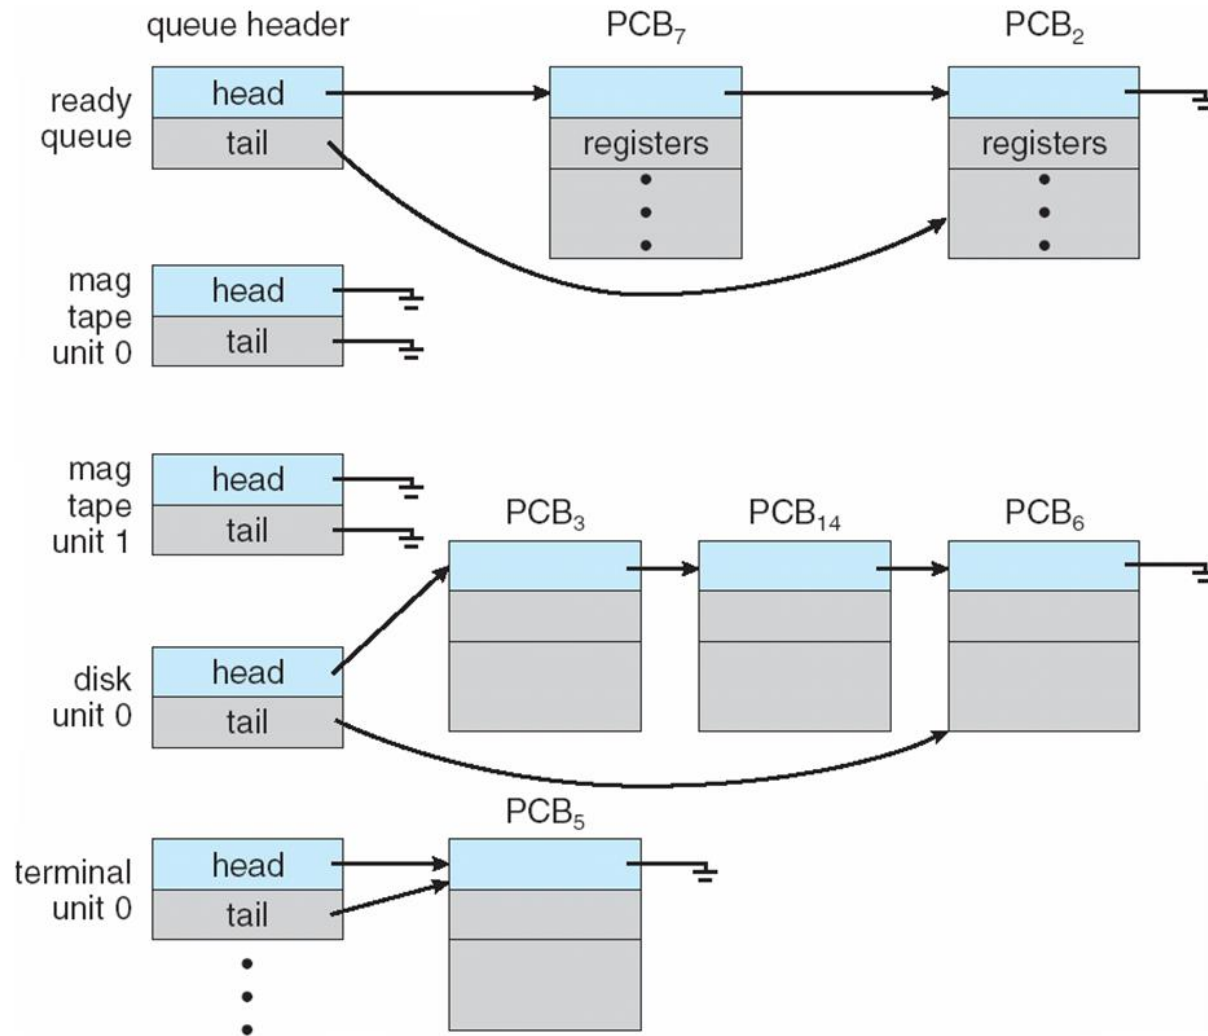

**Context Switch**

# Process Scheduling

- Maximize CPU use, quickly switch processes onto CPU for time sharing.
- Process scheduler selects among available processes for next execution on CPU
- Maintains scheduling queues of processes:-
  - Job queue – set of all processes in the system
  - Ready queue – set of all processes residing in main memory, ready and waiting to execute
  - Device queues – set of processes waiting for an I/O device
  - Processes migrate among the various queues

# Representation of Process Scheduling

# Schedulers

Short-term scheduler (or CPU scheduler) – selects which process should be executed next and allocates CPU

Sometimes the only scheduler in a system

Short-term scheduler is invoked frequently (milliseconds)  $\Rightarrow$  (must be fast)

Long-term scheduler (or job scheduler) – selects which processes should be brought into the ready queue

Long-term scheduler is invoked infrequently (seconds, minutes)  $\Rightarrow$  (may be slow)

The long-term scheduler controls the degree of multiprogramming

Processes can be described as either:

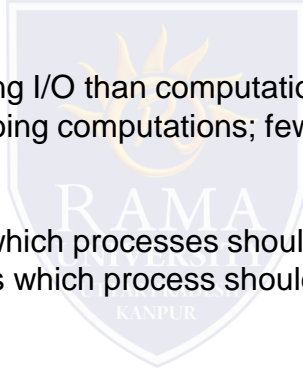

I/O-bound process – spends more time doing I/O than computations, many short CPU bursts

CPU-bound process – spends more time doing computations; few very long CPU bursts

Long-term scheduler strives for good *process mix*

*Long-term scheduler* (or job scheduler) – selects which processes should be brought into the ready queue

*Short-term scheduler* (or CPU scheduler) – selects which process should be executed next and allocates CPU

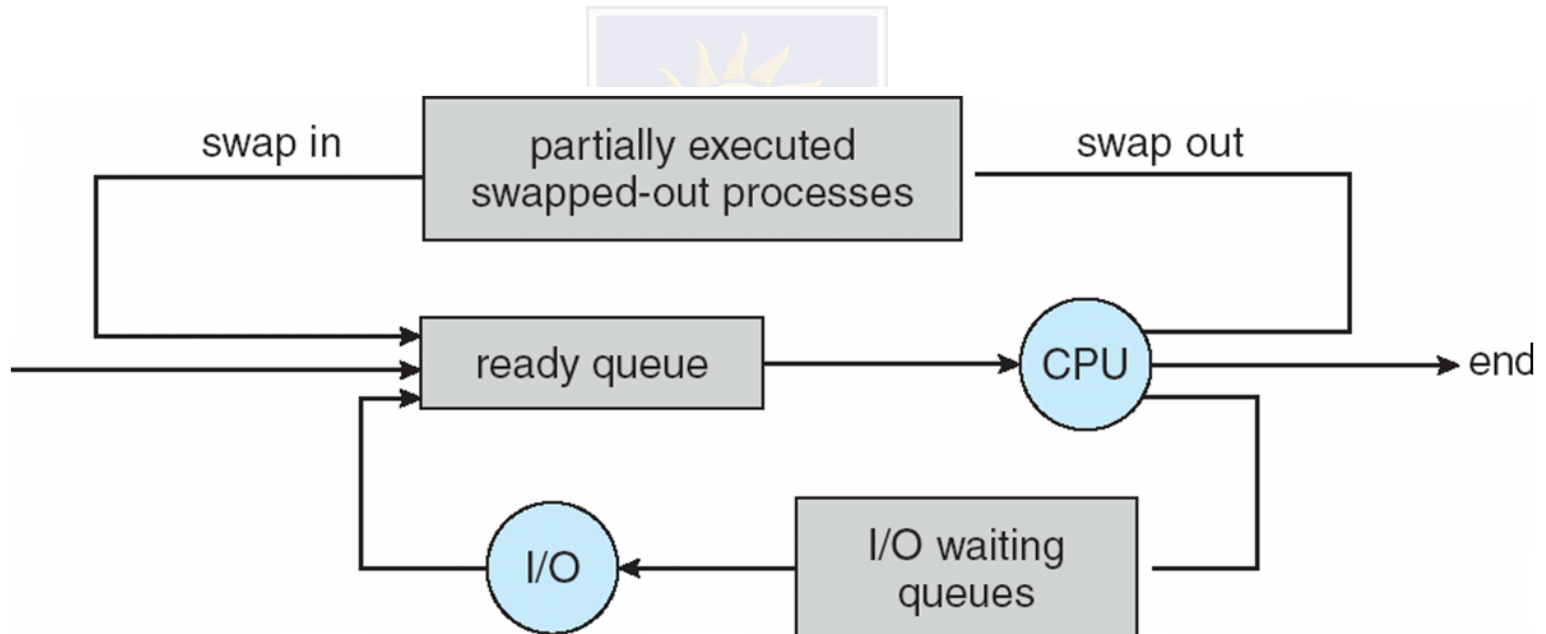

- Short-term scheduler is invoked very frequently (milliseconds)  $\Rightarrow$  (must be fast)
- Long-term scheduler is invoked very infrequently (seconds, minutes)  $\Rightarrow$  (may be slow)
- The long-term scheduler controls the degree of multiprogramming
- Processes can be described as either:
  - *I/O-bound process* – spends more time doing I/O than computations, many short CPU bursts
  - *CPU-bound process* – spends more time doing computations; few very long CPU bursts

# Addition of Medium Term Scheduling

Medium-term scheduler can be added if degree of multiple programming needs to decrease

Remove process from memory, store on disk, bring back in from disk to continue execution: swapping

# Context Switch

- When CPU switches to another process, the system must save the state of the old process and load the saved state for the new process.
- Context-switch time is overhead; the system does no useful work while switching.
- Time dependent on hardware support

# Process Creation

- Parent process creates children processes, which, in turn create other processes, forming a tree of processes.
- Resource sharing
  - Parent and children share all resources.
  - Children share subset of parent's resources.
  - Parent and child share no resources.
- Execution
  - Parent and children execute concurrently.
  - Parent waits until children terminate.
- Address space
  - Child duplicate of parent.
  - Child has a program loaded into it.
- UNIX examples
  - fork system call creates new process
  - exec system call used after a fork to replace the process' memory space with a new program

Resource sharing means.....

- A. Parent and children share all resources.
- B. Children share subset of parent's resources
- C. All sharable
- D. None

Short-term scheduler (or CPU scheduler) –selects which process should be executed.....

- A. next and allocates CPU
- B. previous and allocates CPU
- C. Last process and allocates CPU
- D. None

Context switch....

- A. When CPU switches to another process
- B. the system must save the state of the old process
- C. load the saved state for the new process
- D. All of these

UNIX uses.....

- A. fork system call creates new process
- B. Terminate process
- C. memory space with a new program
- D. Loading with process
